**WHO:** International Osteoporosis Foundation

**WHAT/WHEN:** Last week the World Congress on Osteoporosis, Osteoarthritis and Musculoskeletal Diseases (WCO-IOF-ESCEO 2015) hosted a symposium showing a potential new metric of bone health; functional bone performance, and an opportunity for ambulatory individuals with low BMD to increase both BMD and function when absorbing impact, in an effort to avoid fracture. Dr. Cory Huck of the University of Wisconsin, School of Health Promotion and Human Development, at Stevens Point, and Dr. John Jaquish, Chief Science & Technology Officer of Performance Health Systems, conducted the analysis. A summary of the findings is below:

- **Objective:** To determine valid functional bone performance metrics and adaptation from multiple-of-bodyweight (MOB) compressive force loading using an impact level loading exercise apparatus from a population of 2380 adult males and females.
- **Results:** The MOB force/loading levels in the DXA subset (which resulted in a 7% increase in hip BMD, and a 7.7% increase in spinal BMD) was correlated to the MOB forces seen with the larger population showing spine and lower extremity loading with 2.89±1.02 SD and 9.67±3.68 SD MOB, respectively.
- **Conclusion:** This data presents the opportunity for a new metric of functional bone performance, and an opportunity to consider a supplementary treatment option for ambulatory individuals with low BMD.

**WHERE:** World Congress on Osteoporosis, Osteoarthritis and Musculoskeletal Diseases (WCO-IOF-ESCEO 2015) in Milan, Italy.

**ABOUT PERFORMANCE HEALTH SYSTEMS:** Performance Health Systems LLC, the manufacturer of bioDensity™ osteogenic loading devices, specializes in delivering advanced technology solutions through its health and wellness equipment.

FUNCTIONAL BONE PERFORMANCE MEASUREMENTS AND ADAPTATIONS USING NOVEL SELF-APPLIED BONE-LOADING EXERCISE APPARATUS

C. Huck¹, J. Jaquish²

¹University of Wisconsin, School of Health Promotion and Human Development, Stevens Point, Wisconsin, United States, ²Performance Health Systems, Chicago, United States

Objective: To determine valid functional bone performance metrics and adaptations from multiple-of-bodyweight (MOB) compressive force loading using an impact level loading exercise apparatus from a population of 2380 adult males and females.

Materials and Methods: Forces that compress bone stimulate adaptive response of BMD growth, in accordance with Wolff’s Law; bone that can tolerate more load is of greater density [1]. Further, clinical fracture risk assessment is determined by a combination of BMD analysis and level of general physical function (i.e., age/ability) [2]. A novel apparatus that allows for these compressive forces to the level required to have an effect on osteoblastic function has been shown to produce osteogenic effect. This was confirmed in subset test with pre-post DXA in both hip and spine with 14 subjects (P<0.001), who adapted to comfortably tolerate forces of both spine and lower extremity loading with 3.13 and 9.18 MOB respectively [3]. Globally networked osteogenic loading (OL) systems provide standardized protocols. Query for data analysis included patients/subjects who utilized the OL apparatus for 12 or more sessions; partaking in the therapy at a clinically focused, supervised facility for one year.

Results: The MOB force/loading levels in the DXA subset was correlated to the MOB forces seen with the larger population (N = 2380) showing spine and lower extremity loading with 2.89±1.02 SD and 9.67±3.68 SD MOB, respectively.

Conclusion: These data present a new metric of functional bone performance, and an opportunity to consider a supplementary treatment option for ambulatory individuals with low BMD.
